Abstract. We analyze the residuals of GMRES [9], when the method is applied to tridiagonal Toeplitz matrices. We first derive formulas for the residuals as well as their norms when GMRES is applied to scaled Jordan blocks. This problem has been studied previously by Ipsen [5], Eiermann and Ernst [2], but we formulate and prove our results in a different way. We then extend the (lower) bidiagonal Jordan blocks to tridiagonal Toeplitz matrices and study extensions of our bidiagonal analysis to the tridiagonal case. Intuitively, when a scaled Jordan block is extended to a tridiagonal Toeplitz matrix by a superdiagonal of small modulus (compared to the modulus of the subdiagonal), the GMRES residual norms for both matrices and the same initial residual should be close to each other. We confirm and quantify this intuitive statement. We also demonstrate principal difficulties of any GMRES convergence analysis which is based on eigenvector expansion of the initial residual when the eigenvector matrix is ill-conditioned. Such analyses are complicated by a cancellation of possibly huge components due to close eigenvectors, which can prevent achieving well-justified conclusions.

AMS subject classifications. 15A09, 65F10, 65F20

1. Introduction. Consider solving a linear algebraic system \( Ax = b \), real or complex, where \( A \) is an \( N \times N \) nonsingular matrix with GMRES [9]. Starting from an initial guess \( x_0 \), this method computes the initial residual \( r_0 = b - Ax_0 \) and a sequence of iterates, \( x_1, x_2, \ldots \) so that the \( n \)th residual \( r_n = b - Ax_n \) satisfies

\[
\|r_n\| = \|p_n(A)r_0\| = \min_{p \in \pi_n} \|p(A)r_0\|,
\]

where \( \pi_n \) denotes the set of polynomials of degree at most \( n \) with value one at the origin, and \( \| \cdot \| \) denotes the 2-norm. It is easy to see from (1.1), that (in exact arithmetic) the GMRES algorithm terminates, i.e. computes the solution \( x \), in at most \( N \) steps. We also wish to point out that, unless there is well-justified reason for choosing a nonzero initial approximation, one should consider \( x_0 = 0 \) (see [8]).

Suppose that the vectors \( r_0, Ar_0, \ldots, A^n r_0 \) generating the \((n+1)\)st Krylov subspace \( K_{n+1}(A, r_0) = \text{span}\{r_0, Ar_0, \ldots, A^n r_0\} \) are linearly independent. Then \( r_n \) is a nonzero vector and GMRES can not terminate before the step \( n+1 \). Denote by \( K_{n+1} \) the matrix of the Krylov vectors,

\[
K_{n+1} = [r_0, Ar_0, \ldots, A^n r_0] = [r_0, W_n R_n],
\]

where \( W_n \) has orthonormal columns, and \( R_n \) is upper triangular.

In [5, Theorem 2.1] Ipsen shows that \( r_n \) is determined by the first row of the Moore-Penrose pseudoinverse of \( K_{n+1} \),

\[
r_n^T = ||r_n||^2 e_1^T K_{n+1}^+.
\]
Based on this result she argues that as long as the matrix $K_{n+1}$ is well conditioned, the decrease of the GMRES residual norms in the steps 1 to $n$ must be slow. Then she applies this relation to analyze the GMRES behavior for scaled Jordan blocks [5, Theorem 3.1].

In [6, pp. 1505–1506], it is shown that

$$r_n^T = \|r_n\|^2 e_1^T [r_0, W_n]^+, \quad (1.4)$$

which refines Ipsen’s argument about the relation between ill-conditioning of the Krylov matrix and convergence of the GMRES residual norms. The proofs in [6] are based on the elementary geometrical interpretation of the pseudoinverse (orthogonality relations).

In this paper we study the GMRES residuals for linear systems with tridiagonal Toeplitz matrices $T$. We start with results analogous to those of Ipsen for scaled Jordan blocks, and then analyze their extensions. We are particularly interested in the case when the entries on the superdiagonal of $T$ are significantly smaller in modulus (absolute value) than the entries on the subdiagonal. This represents an example of very large eigenvector conditioning (even infinite when the matrix reduces to a scaled Jordan block), i.e., we deal with highly nonnormal matrices. Rather than applying a worst-case analysis based on properties of the matrix $T$ only, we exploit the structure of $T$ and relate the GMRES convergence to the structure and numerical values of the entries of the initial residual $r_0$. This allows qualitative as well as quantitative statements about the influence of $T$ as well as $r_0$ on the GMRES residuals. In proofs we follow, as in [6, pp. 1505–1506], the elementary orthogonality idea.

Analytic results for scaled Jordan blocks and general tridiagonal Toeplitz matrices are given in Sections 2 and 3, respectively. Section 4 shows numerical experiments, and Section 5 contains concluding remarks. In this paper we do not consider rounding errors, i.e. we assume exact arithmetic.

2. Scaled Jordan blocks. For given nonzero parameters $\gamma$ and $\lambda$, consider an $N$ by $N$ scaled Jordan block $J$,

$$J = \gamma S + \lambda I = \gamma (S + \tau I), \quad \tau = \frac{\lambda}{\gamma}, \quad (2.1)$$

where $I$ is the identity and $S = [e_2, \ldots, e_N, 0]$ is the down shift matrix ($e_j$ denotes the $j$th vector of the standard Euclidean basis). The scaling does not affect GMRES convergence; it is used for convenience only. The GMRES residual norms for systems with scaled Jordan blocks have been studied in [2] and in [5, Section 3]. Here we study the same problem, but we formulate and prove our results differently from [2, 5].

**Theorem 2.1.** Suppose that GMRES is applied to a system with the matrix $J = \gamma (S + \tau I)$ and the initial residual $r_0 = [\rho_1, \ldots, \rho_N]^T$. Let $\rho_1$ be the first nonzero entry of $r_0$. Then for $n = 0, 1, \ldots, N - l$ the GMRES residuals satisfy

$$r_n^T = \|r_n\|^2 [1, -\tau, \ldots, (-\tau)^n] [r_0, S r_0, \ldots, S^n r_0]^+, \quad (2.2)$$

$$\|r_n\| \geq \left( \sum_{j=0}^{n} |\tau|^{2j} \right)^{-\frac{1}{2}} \sigma_{\min} ([r_0, S r_0, \ldots, S^n r_0]), \quad (2.3)$$
and \( r_{N-l} = 0 \), where \( \sigma_{\min}(X) \) denotes the minimal singular value of the matrix \( X \). Furthermore, for \( n = 0, 1, \ldots, N - l \),

\[
\|r_n\| \leq (n + 1)^{\frac{1}{2}} \|r_0\| \left( \sum_{j=0}^{n} |t|^2 \right)^{-\frac{1}{2}} .
\]

**Proof.** Since \( K_{n+1}(J, r_0) = K_{n+1}(S, r_0) \) and \( \rho_l \neq 0 \), it is easy to see that for \( n = 0, 1, \ldots, N - l \) the matrices \([r_0, Jr_0, \ldots, Jnr_0]^+\) have full column rank. Hence, for \( n = 0, 1, \ldots, N - l \), the equation (1.3) (see also [6, Theorem 2.1]) shows that

\[
\|r_n\|^2 e_1^T [r_0, Jr_0, \ldots, Jnr_0]^+ = \|r_n\|^2 g_n^T .
\]

The identity \([r_0, Jr_0, \ldots, Jnr_0]^+ [r_0, Jr_0, \ldots, Jnr_0] = I\) gives

\[
g_n^T [r_0, Jr_0, \ldots, Jnr_0] = e_1^T .
\]

We next prove, by induction,

\[
g_n^T [r_0, Sr_0, \ldots, S^n r_0] = [1, -\tau, \ldots, (-\tau)^n] .
\]

Clearly,

\[
0 = g_n^T Jr_0 = \gamma g_n^T Sr_0 + \lambda g_n^T r_0 = \gamma g_n^T Sr_0 + \lambda, \quad \text{i.e.,} \quad g_n^T Sr_0 = -\tau ,
\]

and the general step,

\[
0 = g_n^T J^k r_0 = g_n^T (\gamma S + \lambda I) r_0
\]

\[
= g_n^T \left( \sum_{j=0}^{k} \left( \begin{array}{c} k \\ j \end{array} \right) \gamma^{k-j} \lambda^j S^{k-j} \right) r_0
\]

\[
= \gamma^k g_n^T S^k r_0 + \sum_{j=1}^{k} \left( \begin{array}{c} k \\ j \end{array} \right) \gamma^{k-j} \lambda^j (-\tau)^{k-j}
\]

\[
= \gamma^k g_n^T S^k r_0 - (-\lambda)^{k} + \sum_{j=0}^{k} \left( \begin{array}{c} k \\ j \end{array} \right) (-\lambda)^{k-j} \lambda^j
\]

\[
= \gamma^k g_n^T S^k r_0 - (-\lambda)^{k} ,
\]

from which \( g_n^T S^k r_0 = (-\tau)^{k} \). Multiplying (2.6) from the right by the pseudoinverse \([r_0, Sr_0, \ldots, S^n r_0]^+\) and using the fact that \( g_n \) lies in the range of \([r_0, Sr_0, \ldots, S^n r_0] \) proves (2.2). Then (2.3) follows in an obvious way. In order to show (2.4), we denote the \( N \) by \( n + 1 \) matrix on the left hand side and the vector on the right hand side of (2.6) by \( R \) and \( t \), respectively. Then, using (2.5),

\[
\|r_n\| = \|g_n\|^{-1} \leq \|R\| \|t\|^{-1} \leq \|R\|_F \|t\|^{-1} \leq (n + 1)^{\frac{1}{2}} \|r_0\| \|t\|^{-1} ,
\]

where \( \| \cdot \|_F \) denotes the Frobenius norm of a matrix. \( \square \)
Writing (2.6) for the maximal \( n = N - l \) in a transposed form gives the upper triangular system for the nonzero entries of \( g_{N-l} = [0, \ldots, 0, \chi_l, \chi_{l+1}, \ldots, \chi_N] \),

\[
\begin{bmatrix}
p_{l1} & p_{l+1} & \cdots & p_{N1} \\
p_{l2} & \cdots & \cdots & p_{N2} \\
\vdots & \ddots & \ddots & \vdots \\
p_{lN} & & & p_{NN}
\end{bmatrix}
\begin{bmatrix}
\chi_l \\
\chi_{l+1} \\
\vdots \\
\chi_N
\end{bmatrix}
= \begin{bmatrix}
1 \\
-\tau \\
\vdots \\
(-\tau)^{N-l}
\end{bmatrix}.
\]

(2.7)

The identity (2.5) now immediately implies the following.

**Corollary 2.2.** With the assumptions and notation of Theorem 2.1,

\[
r_{N-l} = \|r_{N-l}\|^2 g_{N-l}, \quad \text{and} \quad \|r_{N-l}\| = \|g_{N-l}\|^{-1},
\]

where the nonzero entries of \( g_{N-l} \) are determined from (2.7) by back substitution.

Theorem 2.1 and Corollary 2.2 show how the GMRES residuals depend on \( J \) (particularly on the ratio of \( \lambda \) and \( \gamma \)) and the structure of \( r_0 \). The bound (2.4) is interesting for large values of \( |\tau| \) only, i.e., for diagonally dominant matrices \( J \). In the following examples we give explicit formulas for the \( n \)th GMRES residual and its norm for some specific initial residuals.

**Example 2.3.** Suppose that \( r_0 = e_l \) is the \( l \)th standard basis vector. Then for \( n = 0, 1, \ldots, N - l \), \([r_0, Sr_0, \ldots, S^nr_0] = [e_l, e_{l+1}, \ldots, e_{l+n}]\). Hence (2.2) yields

\[
r_n^T = \|r_n\|^2 [0, \ldots, 0, 1, -\tau, \ldots, (-\tau)^n, 0, \ldots, 0],
\]

where \( r_n^T \) has \( l - 1 \) leading and \( N - n - l \) trailing zeros, respectively. Taking norms on both sides shows that

\[
\|r_n\| = \left( \sum_{j=0}^{n} |\tau|^{2j} \right)^{-\frac{1}{2}},
\]

(2.9)

i.e., that equality holds in (2.3) with \( \sigma_{\min} ([r_0, Sr_0, \ldots, S^nr_0]) = 1 \). We see that for \( r_0 = e_l \), the GMRES residual norms suffer from slow convergence until the very last step whenever \( |\tau| \leq 1 \). In their unpublished note [2], Eiermann and Ernst give a proof of (2.9) as well as a slightly weaker form of (2.4) based on a formula for the GMRES minimizing polynomial. They also point out that (2.9) is equivalent to the identity

\[
\min_{p \in \pi_n} \left\{ \sum_{j=0}^{n} \left( \frac{p^{(j)}(\tau)}{j!} \right)^2 \right\} = \left( \sum_{j=0}^{n} |\tau|^{2j} \right)^{-1},
\]

where \( p^{(j)}(\tau) \) denotes the \( j \)th derivative of the polynomial \( p(\tau) \). This can be of interest independently of the GMRES context.

**Example 2.4.** Consider the particular case \( r_0 = e \equiv [1, 1, \ldots, 1]^T \). Then for \( n = 1, 2, \ldots, N - 1 \),

\[
[e, Se, \ldots, S^ne]^+ = \left[ e_1, -e_1 + e_2, \ldots, -e_{n-1} + e_n, -e_n + \frac{1}{N-n}S^ne \right]^T,
\]
which can easily be verified using the four Moore-Penrose conditions, see, e.g., [11, p. 102]. The GMRES residuals are therefore given by

$$r_n^T \frac{r_n}{\|r_n\|^2} = [1, -\tau, \ldots, (-\tau)^n] [e, S e, \ldots, S^n e]^+$$

$$= \left[ 1 + \tau, -(\tau + \tau^2), \ldots, (-1)^{n-1}(\tau^{n-1} + \tau^n), \frac{(-\tau)^n}{N-n}, \ldots, \frac{(-\tau)^n}{N-n} \right],$$

and hence

$$\|r_n\| = \left( |1 + \tau|^2 \sum_{k=0}^{n-1} |\tau|^{2k} + \frac{|\tau|^{2n}}{N-n} \right)^{-\frac{1}{p}}.$$

Similarly to the case \( r_0 = e_1 \), the GMRES residual norms converge for \( r_0 = e \) slowly until the very last step whenever \( |\tau| \leq 1 \). Unlike in the case \( r_0 = e_1 \), for \( r_0 = e \) the GMRES convergence depends on the sign of the real part of \( \tau \). In particular,

$$\|r_n\| = \left( \frac{N-n}{2n(N-n)+1} \right)^{\frac{1}{p}}, \quad \text{for } \tau = 1,$$

$$\|r_n\| = (N-n)^{\frac{1}{p}}, \quad \text{for } \tau = -1.$$ 

Thus the stagnation is more severe when \( \tau = -1 \) (recall that \( \|r_0\| = N^{\frac{1}{p}} \)).

3. Tridiagonal Toeplitz matrices. Given nonzero parameters \( \gamma, \lambda \) and \( \mu \), consider an \( N \) by \( N \) tridiagonal Toeplitz matrix \( T \),

$$T = \gamma S + \lambda I + \mu S^T \equiv \gamma (S + \tau I + \zeta S^T), \quad \tau \equiv \frac{\lambda}{\gamma}, \quad \zeta \equiv \frac{\mu}{\gamma}.$$ 

Adding a nonzero superdiagonal \( \mu S^T \) to \( J \) in (2.1) causes the resulting matrix \( T \) to have \( N \) distinct eigenvalues,

$$\sigma_k = \lambda + (\gamma \mu)^{\frac{1}{p}} \omega_k, \quad \omega_k \equiv 2 \cos \frac{k\pi}{N+1}, \quad k = 1, \ldots, N,$$

with the corresponding normalized eigenvectors given by

$$y_k = \nu_k [\Delta u_k], \quad k = 1, \ldots, N,$$

where

$$u_k = \left( \frac{2}{N+1} \right)^{\frac{1}{p}} \left[ \sin \frac{k\pi}{N+1}, \ldots, \sin \frac{Nk\pi}{N+1} \right]^T,$$

$$\Delta = \text{diag} \left( \zeta^{-\frac{1}{2}}, \zeta^{-1}, \ldots, \zeta^{-\frac{N}{2}} \right),$$

$$\nu_k = \left( \frac{2}{N+1} \sum_{j=1}^{N} \zeta^{-j} \sin^2 \frac{jk\pi}{N+1} \right)^{-\frac{1}{p}}.$$
see, e.g., [10, pp. 113-115]. Please note that the matrix \( U = [u_1, \ldots, u_N] \) represents the real orthonormal and symmetric eigenvector matrix of any \( N \) by \( N \) symmetric (possibly complex) tridiagonal Toeplitz matrix. The eigenvector matrix \( Y = [y_1, \ldots, y_N] \) of \( T \) is, apart from the normalization, obtained from \( U \) by scaling the rows by the powers of \( \zeta^{-j} \). Hence the condition number of \( Y \) equals \( \max(\|\zeta\|^{-N}, \|\zeta\|^{-N}) \).

When \( |\gamma| \approx |\mu| \), meaning \( |\gamma| \approx 1 \), then \( Y \) is well-conditioned and one may base the GMRES convergence analysis on the eigenvalues of \( T \) and the components of \( r_0 \) in the direction of the individual eigenvectors of \( T \).

This paper is motivated by the application of GMRES to convection-diffusion problems with dominating convection [7]. Then the interesting case is characterized by \(|\gamma| \approx |\lambda| \gg |\mu| \), meaning \(|\gamma| \approx 1 \) and \(|\zeta| \ll 1 \). The principal question is: To which extent does the behavior of the GMRES residual for \( T \) and a given \( r_0 \) resemble the behavior of the GMRES residual for the corresponding \( J \) and the same \( r_0 \)? We focus on this question but we also present some general statements valid for arbitrary nonzero values of \( \gamma, \lambda \) and \( \mu \).

We would like to stress the following subtle point: When \(|\gamma| \) is small, then the matrix \( T \) can be viewed as a small perturbation of the matrix \( J \). It is therefore tempting to conclude that for each given \( r_0 \) the Krylov subspaces generated by \( T \) and \( J \) are in some sense close to each other. This would imply that generally the GMRES residual norms for \( J \) and \( r_0 \) are close to the GMRES residual norms for \( T \) and \( r_0 \). However, it is well known that a small perturbation of a general matrix does not ensure a small change of the Krylov subspace, not even when the matrix is symmetric positive definite (an instructive example is given below). It is the structure of \( J \) and \( T \) that makes such arguments applicable and our analysis possible.

### 3.1. Explicit mapping.

The standard approach to GMRES convergence analysis is based on the eigendecomposition \( T = YDY^{-1}, D = \text{diag}(\sigma_1, \ldots, \sigma_N) \), giving

\[
\|r_n\| = \|Yp_n(D)Y^{-1}r_0\| = \min_{p \in \mathbb{P}_n} \|Yp(D)Y^{-1}r_0\|
\]

\[
\leq \|Y\|\|Y^{-1}\|\|r_0\| \min_{p \in \mathbb{P}_n} \max_k |p(\sigma_k)|,
\]

see [3, Theorem 5.4], [9, Proposition 4]. The resulting worst case bound (3.5) frequently is the basis for discussions of GMRES convergence. However, it does not take into account the fact that for some initial residuals GMRES may behave very differently than for others. In practical problems we work with some particular initial residuals and we are rarely interested in the worst case behavior. Moreover, when the eigenvector matrix \( Y \) is ill-conditioned, then some components of the vector \( Y^{-1}r_0 \) can be very large, potentially much larger than \( \|r_0\| \). On the other hand, the norm of the linear combination \( Y[p_n(D)Y^{-1}r_0] \) in (3.4) is bounded from above by \( \|r_0\| \).

This linear combination therefore can contain a significant cancellation, which is not reflected in the minimization problem (3.5). Hence the principal weakness of (3.5) in case of ill-conditioned eigenvectors is not the potentially large multiplicative factor \( \|Y\|\|Y^{-1}\|\|r_0\| \), in our case equal to \( \max(\|\zeta\|^{N-1}, \|\zeta\|^{-N}) \). The principal weakness is rather the minimization problem itself. In general, any description of GMRES convergence using the possibly large coordinates \( Y^{-1}r_0 \) of \( r_0 \) in the eigenvector basis, and the mapping from \( Y^{-1}r_0 \) to the \( n \)th GMRES residual \( r_n \), should be applied with proper care for the cancellation that might occur in the presence of close eigenvectors. For more discussion on this topic we refer to [7] and [12]. In the following we will show the difference when the mapping from \( Y^{-1}r_0 \) to \( r_n \) is replaced by the mapping from \( r_0 \) to \( r_n \).
Let us examine the identity
\begin{equation}
(3.6) \quad r_n = p_n(T) r_0 = \Delta U p_n(D) U \Delta^{-1} r_0.
\end{equation}
We interpret $p_n(T)$ as the mapping from $r_0$ to $r_n$, and denote, for simplicity, $p_n(T) = C_n$. The entries $c_n^{(j,k)}$ of $C_n$, $j,k = 1,2,\ldots,N$, are given by
\begin{equation}
(3.7) \quad c_n^{(j,k)} = e_j^T C_n e_k = e_j^T \Delta U p_n(D) U \Delta^{-1} e_k = \zeta^{k-j} u_j^T p_n(D) u_k.
\end{equation}
The $j$th entry of $r_n$ can be expressed as
\begin{equation}
(3.8) \quad e_j^T r_n = e_j^T C_n r_0 = \sum_{k=1}^{N} c_n^{(j,k)} p_k.
\end{equation}
Note that since $T$ is tridiagonal, the matrices $T^n$ and thus the matrices $C_n$, for $n = 0,1,\ldots,N-1$, in general have exactly $n$ nonzero sub- and $n$ nonzero superdiagonals. In particular, $c_n^{(j,k)} = 0$ for $|j-k| > n$.

**Theorem 3.1.** For each $n$ until GMRES terminates the mapping $C_n$ from $r_0$ to $r_n$ represents a banded matrix with $2n+1$ nonzero diagonals. We denote the column vectors formed by the entries of each diagonal (ordered from the most outer subdiagonal to the most outer superdiagonal) by
\begin{equation}
(3.9) \quad c_n^{(-n)}, c_n^{(-n+1)}, \ldots, c_n^{(0)}, \ldots, c_n^{(n-1)}, c_n^{(n)}.
\end{equation}
Then the subdiagonals and superdiagonals are related by
\begin{equation}
(3.10) \quad c_n^{(d)} = \zeta^d c_n^{(-d)},
\end{equation}
and the $n$th GMRES residual can therefore be written in the form
\begin{equation}
(3.11) \quad r_n = C_n r_0 = \sum_{d=0}^{n} [S^d r_0] \odot \begin{bmatrix} 0_d & c_n^{(-d)} \end{bmatrix} + \zeta \sum_{d=1}^{n} \zeta^{d-1} ([S T]^d r_0] \odot \begin{bmatrix} c_n^{(-d)} \\ 0_d \end{bmatrix},
\end{equation}
where $a \odot b$ denotes the element-by-element multiple (Hadamard product) of the vectors $a$ and $b$, and $0_d$ denotes the zero vector of length $d$.

**Proof.** For a given $n$, and $d$ fixed between 1 and $n$, the vector $c_n^{(-d)}$ representing the $d$th subdiagonal consists of the entries $c_n^{(j,j-d)}$, $j = d+1,\ldots,N$. The manipulations
\begin{align*}
c_n^{(j,j-d)} &= \zeta^{-d} u_j^T p_n(D) u_{j-d} \\
&= \zeta^{-d} (\zeta^d u_j^T p_n(D) u_j) \\
&= \zeta^{-d} c_n^{(j,d-j)}
\end{align*}
finish the proof of (3.9). Relation (3.10) is an obvious consequence of (3.9).

When $|\zeta| \ll 1$, the strictly upper triangular part of the mapping $C_n$ is much less significant than its lower triangular part (including the main diagonal). The significance of the superdiagonals is exponentially decreasing with the distance from the main diagonal. Since the proof of Theorem 3.1 does not use that $p_n$ is the GMRES polynomial, the statement can be reformulated for any matrix polynomial $p(T)$, where $T$ is a tridiagonal Toeplitz matrix.
Using (3.8),

\begin{equation}
\| r_n \|^2 = \sum_{j=1}^{N} | c_j^T r_n |^2 = \sum_{j=1}^{N} \sum_{k=1}^{N} c_n^{(jk)} p_k^2 .
\end{equation}

Since \( C_0 = I \), this formula for \( n = 0 \) reduces to

\begin{equation}
\| r_0 \|^2 = \sum_{j=1}^{N} \left( \sum_{k=1}^{N} c_0^{(jk)} p_k \right)^2 = \sum_{k=1}^{N} | p_k |^2 .
\end{equation}

A comparison of (3.11) and (3.12) shows that the decrease of the GMRES residual norms is controlled by the behavior of the individual entries \( c_n^{(jk)} \) defined in (3.7). Moreover,

\begin{equation}
\| r_n \| \leq \| r_0 \| \| C_n \| \leq \| r_0 \| \| C_n \|_F .
\end{equation}

These bounds are different from the usual worst-case convergence bounds in that \( C_n \) is determined by \( p_n \) which depends on the particular \( r_0 \).

The individual entries of the matrices \( C_n \) do not decrease monotonically, but their behavior is typically very different from the behavior of the entries of the mapping \( Y p_n(D) \) from \( Y^{-1} r_0 \) to \( r_n \) in (3.4). We do not quantify this in a statement, but present a qualitative argument and experiments. The only term which can seemingly make \( c_n^{(jk)} \) large is \( \zeta^{j-k} \). When e.g., \( |\zeta| \ll 1 \), then for \( j > k \) this factor becomes large.

However, \( c_n^{(jk)} \) are the entries of the matrix \( C_n = p_n(T) \). Therefore we may expect that the individual nonzero \( c_n^{(jk)} \) are of moderate size, and mostly decreasing (though possibly very slowly) with \( n \), which makes the inequalities (3.13) reasonable. The fact that each iteration step \( n \) introduces a new nonzero subdiagonal in the mapping from \( r_0 \) to \( r_n \) hints that when \( |\gamma| \approx |\lambda| \gg |\mu| \), i.e. \( |\gamma| \approx 1 \gg |\zeta| \), the GMRES convergence may be slow.

We emphasize that these considerations about \( C_n \) and convergence of GMRES are based on the particular tridiagonal Toeplitz structure of \( T \). On the other hand, when the components of \( Y^{-1} r_0 \) are large, any approach based on \( Y p_n(D) \) can hardly lead to a well justified insight, even when the special structure of \( T \) is exploited.

In Fig. 3.1 we plot the values \( \log_{10}(|c_n^{(jk)}|) \), \( j, k = 1, \ldots, 15 \), for \( n = 2, 6, 10, 14 \), computed when GMRES is applied to the 15 by 15 matrix \( T_1 = S + I + 0.01 S^T \) and the initial residual \( r_0 = e \). Corresponding results for \( T_1 \) and \( r_0 = \text{rand}(15,1) \) are shown in Fig. 3.2 (\texttt{rand} is the pseudo-random number generator in MATLAB), and Fig. 3.3 shows results for the diagonally dominant matrix \( T_2 = S + 2I + 0.01 S^T \) and \( r_0 = e \). In Fig. 3.4 we plot the respective GMRES residual norms and in Fig. 3.5 the values \( \| C_n \|_F \), representing an upper bound on \( \| r_n \| / \| r_0 \| \), cf. (3.13).

In Figs. 3.1–3.3 we see a decrease of \( |c_n^{(jk)}| \) on the superdiagonals of \( C_n \) that is exponential in the distance from the main diagonal. Hence in the individual sums \( \left| \sum_{k=1}^{N} c_n^{(jk)} p_k \right|^2 \), \( j = 1, \ldots, N \), on the right hand side of (3.11) only the terms for \( j \geq k \) play a significant role.

For \( T_1 \) and \( r_0 = e \) as well as \( r_0 = \text{rand}(15,1) \), the significant entries \( c_n^{(jk)} \) maintain approximately the same orders of magnitude throughout the GMRES iteration. Correspondingly, the residual norms (solid and dash-dot curves in Fig. 3.4) decrease very slowly until the very last step. The initial residual \( r_0 = e \) presents a case that
yields almost a perfect plateau of significant $|c_n^{(jk)}|$ in every step. The variation of the entries in $r_0 = \text{rand}(15,1)$ causes a larger variation among the absolute values of the significant entries of $C_n$. For $T_2$ and $r_0 = e$, GMRES converges faster (cf. the dashed curve in Fig. 3.4) since all significant entries of $C_n$ decrease noticeably in magnitude in every step. A comparison of Fig. 3.4 and Fig. 3.5 illustrates, that the inequalities (3.13) are for our data quite sharp, and, consequently, that there is no significant cancellation among the individual terms in (3.11).

In the following subsection we develop an analogue of Theorem 2.1 for tridiagonal Toeplitz matrices.

3.2. Extension of the bidiagonal analysis. For each scaled (lower bidiagonal) Jordan block $J$ and each $r_0$ it is easy to see when GMRES terminates: If $\rho_1$ is the first nonzero entry of $r_0$, then GMRES applied to $J$ and $r_0$ terminates in exactly $N - l + 1$ steps giving $r_{N-l-1} \neq 0$ and $r_{N-l+1} = 0$. For a tridiagonal Toeplitz matrix $T$ with nonzero sub- and superdiagonal the situation is more complicated. Here the total number of GMRES steps for a given nonzero pattern of $r_0$ can depend on the actual numerical values of its nonzero entries. However, since we are not interested in conditions for termination of GMRES in a given number of steps, we will not specify this number and merely assume that it is greater than $N - l$.

**Theorem 3.2.** Suppose that GMRES is applied to a system with the matrix $T = \gamma(S + \tau I + S^T)$ and the initial residual $r_0 = [\rho_1, \ldots, \rho_N]^T$. Let $\rho_1$ be the first nonzero entry of $r_0$. Moreover, suppose that $r_0$ has at least $N - l$ nonzero components in the directions of the individual eigenvectors of the matrix $T$ (GMRES does not
Fig. 3.2. The values $\log_{10}(|c_{nk}^{(jk)}|)$ for $j, k = 1, \ldots, N$ and $n = 2$ (top left), 6 (top right), 10 (bottom left), 14 (bottom right), computed when GMRES is applied to the 15 by 15 matrix $T_1 = S + I + 0.001 S^T$ and $r_0 = \text{rand}(15, 1)$.

Fig. 3.3. The values $\log_{10}(|c_{nk}^{(jk)}|)$ for $j, k = 1, \ldots, N$ and $n = 2$ (top left), 6 (top right), 10 (bottom left), 14 (bottom right), computed when GMRES is applied to the 15 by 15 matrix $T_2 = S + 2I + 0.01 S^T$ and $r_0 = e$. 
CONVERGENCE OF GMRES FOR TRIDIAGONAL TOEPLITZ MATRICES

The values \( \| C_n \|_{\mathcal{F}} \) for \( T_1 = S + I + 0.01 SP^T \) and \( r_0 = e \) (solid), \( T_1 \) and \( r_0 = \text{rand}(15,1) \) (dash-dot), \( T_2 = S + 2I + 0.01 SP^T \) and \( r_0 = e \) (dashed).

terminate in the first \( N - l \) steps. Then for \( n = 0, 1, \ldots, N - l \) the GMRES residuals satisfy

\[
\begin{align*}
(3.14) \quad r_n^T = \| r_n \|^2 & \left[ 1, -\tau, \ldots, (-\tau)^n \right] \left[ r_0, (S + \zeta P^T)r_0, \ldots, (S + \zeta P^T)^n r_0 \right]^+, \\
(3.15) \quad \| r_n \| & \geq \left( \sum_{j=0}^{n} |\tau|^{2j} \right)^{-\frac{1}{2}} \sigma_{\min} \left( [r_0, (S + \zeta P^T)r_0, \ldots, (S + \zeta P^T)^n r_0] \right).
\end{align*}
\]
Proof. For \( n = 0, 1, \ldots, N - l \), the matrix \([r_0, Tr_0, \ldots, T^nr_0]\) has full column rank. The rest is similar to the proof of Theorem 2.1, with \( T \) and \( S + \zeta S^T \) taking over the roles of \( J \) and \( S \), respectively. Indeed,
\[
r_n^T = \|r_n\|^2 e_1^T [r_0, Tr_0, \ldots, T^nr_0]^+ = \|r_n\|^2 g_n^T,
\]
from which we receive \( g_n^T [r_0, Tr_0, \ldots, T^nr_0] = e_1^T \). Then
\[
0 = g_n^T Tr_0 = \gamma g_n^T (S + \zeta S^T) r_0 + \lambda g_n^T r_0,
\]
i.e., \( g_n^T (S + \zeta S^T) r_0 = -\tau \), and an induction shows that in fact
\[
g_n^T [r_0, (S + \zeta S^T)r_0, \ldots, (S + \zeta S^T)^nr_0] = [1, -\tau, \ldots, (-\tau)^n].
\]
Now note that
\[
g_n \in \text{span}\{r_0, Tr_0, \ldots, T^nr_0\} = \text{span}\{r_0, (S + \zeta S^T)r_0, \ldots, (S + \zeta S^T)^nr_0\}.
\]
A multiplication of (3.16) from the right with \( \zeta \) yields (3.14). The lower bound (3.15) is a direct consequence. \( \Box \)

Consider, for simplicity, the iteration step \( n = N - l \). The principal difference between the cases with \( J \) and \( T \) is in the form of (2.7) and (3.16). The system of equations (3.16) is for \( l \neq 1 \) underdetermined, and its system matrix is constructed from \( r_0 \) in a much more complicated way than in (2.7). However, the system matrix in (3.16) can be written in the form
\[
[r_0, (S + \zeta S^T)r_0, \ldots, (S + \zeta S^T)^nr_0]^+ = [O, R] + \zeta P,
\]
where \( O \) denotes the \( N-l+1 \) by \( l-1 \) zero matrix, and \( R \) the upper triangular matrix described in (2.7). The columns of \( P^T \) are given by
\[
p_j = \zeta^{-1} \{ (S + \zeta S^T)^j - S^j \} r_0, \quad \text{for} \quad j = 0, 1, \ldots, N - l.
\]
Since \( S \) and \( S^T \) do not commute, \( (S + \zeta S^T)^j \) cannot be evaluated by the binomial theorem. However, for \( j = 1, \ldots, N - l \), this expression can be formally written as
\[
(S + \zeta S^T)^j = \Sigma_{j,0} + \zeta \Sigma_{j,1} + \ldots + \zeta^{j-1} \Sigma_{j,1} + \zeta^j \Sigma_{j,j}.
\]
Here \( \Sigma_{j,k} \) denotes the sum of all possible matrix products involving \( j - k \) times the matrix \( S \) and \( k \) times the matrix \( S^T \). In particular, \( \Sigma_{j,0} = S^j \) and \( \Sigma_{j,j} = (S^T)^j \). Consequently, for \( j = 1, \ldots, N - l \),
\[
p_j = (\Sigma_{j,1} + \zeta \Sigma_{j,2} + \ldots + \zeta^{j-2} \Sigma_{j,j-1} + \zeta^{j-1} \Sigma_{j,j}) r_0.
\]
Note that the matrix \( \Sigma_{j,k} \) is, for \( 1 \leq j \leq N - l \) and \( 1 \leq k \leq j \), the sum of \( \binom{j}{k} \) products of shift matrices, and that \( \|\Sigma_{j,k}\| \leq \binom{j}{k} \). Therefore, assuming \( |\zeta| \ll (j-1)^{-1},
\]
\[
\|p_j\| \leq \|r_0\| \sum_{k=1}^{j} |\zeta|^{k-1} \binom{j}{k} = j \|r_0\| (1 + O(|\zeta|))
\]
where $O(z)$ is bounded from above by $z$ multiplied by a constant (here close to one). When $|\zeta| \ll (N - l)^{-\frac{1}{2}}$, $$(N - l)^{-\frac{1}{2}} \max_j \|p_j\| \leq \|P\| \leq (N - l)^{\frac{1}{2}} \|r_0\| \left(1 + O((N - l)^{-\frac{1}{2}})\right).$$

The system (3.17) can then be considered a small perturbation of the upper triangular system (2.7), extended by a zero block.

We will now use this perturbation idea for analyzing when GMRES applied to $T$ and $r_0$ behaves similarly to GMRES applied to $J$ and $r_0$. As mentioned above, this phenomenon depends in a complicated way on the initial residual $r_0$, cf. (3.16) and (3.17). Any general result with a nontrivial quantitative meaning can therefore be expected to reflect this complicated nature. In the following we have chosen to preserve a quantitative character of the bounds at the price of an assumption on $R^{-1}P$.

We will use the following notation. The residual for GMRES applied to $N$ with $r_0$, and the auxiliary vector obtained as a solution of (2.7) will be denoted by $r_n^{(T)}$ and $g^{(T)}$ respectively. Analogously, $r_n^{(J)}$ respectively $g^{(J)}$ will denote the residual for GMRES applied to $T$ with $r_0$, respectively the minimum norm solution of (3.16). As above, let $r_0 = [\rho_1, \ldots, \rho_N]^T$ with $\rho_1$ being its first nonzero entry. As in Theorem 3.2 we will assume that GMRES applied to $T$ with $r_0$ does not terminate in the first $N - l$ steps. Then from (3.16),

$$g^{(T)}_{N-l} = ([O, R] + \zeta P)^+ [1, -\tau, \ldots, (-\tau)^{N-l}]^T = ([O, I] + \zeta R^{-1}P)^+ R^{-1}[1, -\tau, \ldots, (-\tau)^{N-l}]^T = ([O, I] + \zeta R^{-1}P)^+ g^{(J)}_{N-l}.$$ 

Taking norms,

$$\|([O, I] + \zeta R^{-1}P)^{-1}\| \|g^{(J)}_{N-l}\| \leq \|g^{(T)}_{N-l}\| \leq \|([O, I] + \zeta R^{-1}P)^+\| \|g^{(J)}_{N-l}\|. \tag{3.20}$$

Assuming that $|\zeta| \|R^{-1}P\| < 1$, $$(1 - |\zeta| \|R^{-1}P\|)^{-1} \leq \|([O, I] + \zeta R^{-1}P)^+\|. \tag{3.21}$$

Considering that $\|r_{N-l}^{(T)}\| = 1/\|g_{N-l}^{(T)}\|$ and $\|r_{N-l}^{(J)}\| = 1/\|g_{N-l}^{(J)}\|$, we proved the following theorem.

**Theorem 3.3.** Using the previous notation and the assumptions of Theorem 3.2, let $|\zeta| \|R^{-1}P\| < 1$. Then the GMRES residuals $r_{N-l}^{(T)}$ and $r_{N-l}^{(J)}$ satisfy the following inequalities,

$$\left(1 + |\zeta| \|R^{-1}P\|\right) \|r_{N-l}^{(J)}\| \geq \|r_{N-l}^{(T)}\| \geq \left(1 - |\zeta| \|R^{-1}P\|\right) \|r_{N-l}^{(J)}\|,$$ 

where $R$ represents the matrix formed by the last $N - l + 1$ columns of the matrix $[r_0, S r_0, \ldots, S^{N-l} r_0]^T$ and $P = [0, S^T r_0, \ldots, S^T r_0, (S + \zeta S^T)^{N-l} - S^{N-l}] r_0]^T$.

The main point can be summarized in the following way. Suppose that a scaled Jordan block $J$ is extended to a tridiagonal Toeplitz matrix $T$ by a superdiagonal of sufficiently small modulus (compared to the modulus of the subdiagonal). Assume
that GMRES for $T$ and $r_0$ terminates no earlier than GMRES for $J$ and $r_0$. Then the convergence of GMRES for $T$ and $r_0$ will be comparable to the convergence of GMRES for $J$ and $r_0$. We next consider two examples illustrating our results.

**Example 3.4.** Suppose that $r_0 = e_1$. Then for $J$ as well as for $T$ the GMRES algorithm terminates in step $N$. Thus, whenever $|\zeta| \|R^{-1}P\| < 1$, the inequalities (3.21) hold with $l = 1$. Note that for $r_0 = e_1$ we have $R = I$ and $\|r_0\| = 1$, so that

$$(1 + |\zeta| \|P\|) \|r^{(J)}_{N-1}\| \geq \|r^{(T)}_{N-1}\| \geq (1 - |\zeta| \|P\|) \|r^{(J)}_{N-1}\| \geq (1 - |\zeta|(N-1)^{\frac{3}{2}}(1 + O((N-1)^{-\frac{3}{2}}))) \|r^{(J)}_{N-1}\|,$$

when $|\zeta| \ll (N - 1)^{-\frac{3}{2}}$.

**Example 3.5.** For $r_0 = e = [1, 1, \ldots, 1]^T$ we can see one of the main differences between the application of GMRES to linear systems with $J$ and with a general extension of $J$ to the tridiagonal Toeplitz matrix $T$: For any nonzero $\gamma$ and $\lambda$, dim $\mathcal{K}_N(J, e) = N$, and hence GMRES with $J$ and $r_0 = e$ terminates in step $N$. For certain nonzero values of $\lambda$, $\gamma$ and $\mu$, however, dim $\mathcal{K}_N(T, e) < N$, and hence for certain matrices $T$ and $r_0 = e$ the GMRES algorithm terminates earlier than in step $N$.

The prime example for the latter case is given by a symmetric $T$, i.e., $\gamma = \mu$. The normalized eigenvectors of each such matrix are given in (3.3) with $\Delta = I$. These vectors represent discrete sine functions and thus they satisfy certain symmetries. In particular, simple technical manipulations show that

$$u_k^T e = \left(\frac{2}{N+1}\right)^{\frac{1}{2}} \sum_{j=1}^{N} \sin \left(\frac{jk\pi}{N+1}\right)$$

$$= \left(\frac{2}{N+1}\right)^{\frac{1}{2}} \frac{\cos \left(\frac{k\pi}{2(N+1)}\right) - \cos \left(\frac{(2N+1)k\pi}{2(N+1)}\right)}{2\sin \left(\frac{k\pi}{2(N+1)}\right)}$$

$$= \left(\frac{2}{N+1}\right)^{\frac{1}{2}} \frac{\cos \left(\frac{k\pi}{2(N+1)}\right)}{2\sin \left(\frac{k\pi}{2(N+1)}\right)} (1 - (-1)^k)$$

$$= 0, \quad \text{if } k \text{ is even.}$$

When $u_k^T r_0 = 0$, the initial residual $r_0$ has no component in the direction of the eigenvector $u_k$ of $T$. For a symmetric $T$ and $r_0 = e$, GMRES will therefore terminate in step $N/2$ or $(N + 1)/2$ when $N$ is even or odd, respectively. A similar result holds for $\gamma = -\mu$.

In general, however, the normalized eigenvectors of a tridiagonal Toeplitz matrix $T$ are given by $\nu_k[\Delta u_k]$. The components of $r_0 = e$ in the direction of the individual eigenvectors of $T$ are generally given by

$$\nu_k^{-1} (u_k^T \Delta^{-1} e) = \nu_k^{-1} \left(\frac{2}{N+1}\right)^{\frac{1}{2}} \sum_{j=1}^{N} \zeta^{\frac{3}{2}} \sin \left(\frac{jk\pi}{N+1}\right),$$

for $k = 1, \ldots, N$. If $|\zeta| \neq 1$, then the initial residual $r_0 = e$ usually has a nonzero component in the direction of each of the individual eigenvectors of $T$. This implies
that a very small additive perturbation of a symmetric, even positive definite, tridiagonal Toeplitz matrix by $\varepsilon S$ (or by $\varepsilon S^T$) may cause GMRES (with $r_0 = e$) to iterate twice as long until it terminates.

Here we are mainly interested in the case $|\zeta| \ll 1$. Then GMRES for $J$ and $r_0 = e$, and usually also for $T$ and $r_0 = e$, terminates in step $N$. If $|\zeta| \|R^{-1}P\| < 1$, then (3.21) holds with $l = 1$. Since $R^{-1} = I - S^T$ we get $\|R^{-1}\| \leq 2$, and since $\|r_0\| = N^{\frac{1}{4}}$, the lower bound in (3.21) yields

$$\|r^{(T)}_{N-1}\| \geq (1 - |\zeta| \|(I - S^T)P\|) \|r^{(J)}_{N-1}\|$$

$$\geq (1 - 2|\zeta|N^2(1 + O((N-1)^{-\frac{1}{2}}))) \|r^{(J)}_{N-1}\|,$$

when $|\zeta| \ll (N-1)^{-\frac{1}{2}}$. Numerical examples for this bound are given in Section 4. 

**4. Numerical Experiments.** The numerical experiments in this section illustrate main points presented and discussed above.

**Experiment 4.1.** We use the 15 by 15 matrices

$$J = S + I,$$
$$T_1 = S + I + 0.01 S^T,$$
$$T_2 = S + I + 0.03 S^T,$$
$$T_3 = S + I + 0.05 S^T,$$
$$T_4 = S + I + 0.999 S^T,$$

and $r_0 = e$. Since $\dim K_N(J,e) = N$, and $\dim K_N(T_j,e) = N$ for all $j$, GMRES with each of the five matrices and $r_0 = e$ terminates in step $N$. The relevant values for the application of the bound (3.21) are given in the following table:

<table>
<thead>
<tr>
<th>$j$</th>
<th>$\zeta_j$</th>
<th>$|R^{-1}_{j}P_j|$</th>
<th>$\zeta_j |R^{-1}_{j}P_j|$</th>
<th>$1 - \zeta_j |R^{-1}_{j}P_j|$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.01</td>
<td>25.58</td>
<td>0.256</td>
<td>0.744</td>
</tr>
<tr>
<td>2</td>
<td>0.03</td>
<td>29.50</td>
<td>0.885</td>
<td>0.115</td>
</tr>
<tr>
<td>3</td>
<td>0.05</td>
<td>34.33</td>

<td>5.1e+04</td>
<td>*</td>
</tr>
</tbody>
</table>

For $j = 1, 2$, we have $\zeta_j \|R^{-1}_{j}P_j\| < 1$, so that the bounds (3.21) are applicable with $l = 1$. The “*” for $j = 3, 4$ indicates that since $\zeta_j \|R^{-1}_{j}P_j\| > 1$, the lower bound in (3.21) is not applicable.

Figures 4.1 and 4.2 show the GMRES residual norms. Since $\tau = 1$, GMRES converges slowly when applied to $J$ (solid). For $T_1$ (dash-dot) and $T_2$ (dotted), the GMRES residual norms are very close to the ones for $J$. The correspondence between $\|r^{(J)}_{14}\|$ and $\|r^{(T_j)}_{14}\|$, $j = 1, 2$, is even closer than predicted by the bounds (3.21). It is also noteworthy that although this bound is not applicable for $T_3$, the residual norms in this case (dots) are very close to the ones for $J$ as well. The results for $T_4$ (dashed) show that for a larger perturbation (here $\zeta_4 = 0.999$) the $(N-1)$st GMRES residual norm for a tridiagonal Toeplitz matrix can differ significantly from the corresponding one for the Jordan block.

**Experiment 4.2.** In Figure 4.3 we used the 15 by 15 matrices

$$J = S + I,$$
$$T_4 = S + I + 0.999 S^T$$
(as in Experiment 4.1),
$$T_5 = S + I + S^T,$$
Fig. 4.1. Residual norms $\|r_n\|/\|r_0\|$ of GMRES applied to the five different 15 by 15 matrices given in (4.1) and the initial residual $r_0 = \epsilon$.

Fig. 4.2. Close-up of Fig. 4.1

and $r_0 = \epsilon$. This experiment demonstrates the difference in the GMRES residual norm curves for $T_4$ (dash-dot) and $T_5$ (dotted), despite the fact that $T_4 = T_5 - 0.001 S^T$ is only a small perturbation of the symmetric matrix $T_5$. It is interesting to observe that until termination of GMRES for $T_5$ the convergence curves are very close to each other. □
Experiment 4.3. Our last experiment comes from the SUPG discretization of a convection-diffusion model problem with dominating convection. This model problem with rectangular domain, regular grid and a constant grid aligned convection motivated our work leading to the results presented in this paper. Here we use it for a short illustration.

As explained in [1, 2] and [7], the SUPG discretized model operator can be written as an $N^2$ by $N^2$ block-diagonal matrix with $N$ by $N$ nonsymmetric tridiagonal Toeplitz blocks $T_j = \gamma_j (S + \tau_j I + \zeta_j S^T)$, $j = 1, \ldots, N$, on its diagonal. Example values for $|\gamma_j|$ and $|\zeta_j|$, as well as the corresponding quantities related to (3.21) with $N = 15$ and $r_0 = e_1$ are given in Table 4.1.

Figure 4.4 shows the GMRES residual norm curves for the matrices $T_j$, $j = 1, \ldots, 15$, and $r_0 = e_1$. For small $j$ we have $|\gamma_j| \approx 1$, which leads to very slow convergence of GMRES for the corresponding scaled Jordan blocks and $r_0 = e_1$. Simultaneously there holds $|\zeta_j| \ll 1$, so that the convergence for the respective tridiagonal Toeplitz matrices $T_j$ with the same $r_0$ is comparably slow. With increasing $j$, both $|\gamma_j|$ and $|\zeta_j|$ increase, and the speed of convergence of GMRES for $T_j$ (as well as for the corresponding Jordan blocks) and $r_0 = e_1$ increases significantly. The slow convergence of GMRES for the matrices $T_j$ with small indices $j$ translates into initial phase of slow converge of GMRES for the SUPG discretized model operator. The detailed exposition is beyond the scope of this paper, and we refer an interested reader to [7].

5. Conclusions and outlook. Consider GMRES convergence for a matrix $A$ and a given initial residual $r_0$. Let $B$ be a small perturbation of $A$. Does the assumption that $B$ is sufficiently close to $A$ guarantee that the GMRES residuals for $A$ with $r_0$ are at every iteration step close to the GMRES residuals for $B$ with $r_0$? A related question, though in a different context and without the dependence on the

Fig. 4.4. Residual norms \(||r_n||/||r_0||\) of GMRES applied to 15 by 15 matrices \(T_j, j = 1, \ldots, 15\), representing the tridiagonal Toeplitz blocks on the diagonal of a SUPG discretized convection-diffusion model operator, see [7], with the initial residuals \(r_0 = e_1\).

initial residual, which we consider vital, was recently also considered by Huhtanen and Nevanlinna [4]. Motivated by applications in convection-diffusion problems [7], this paper studies this question for \(A \equiv J = \gamma S + \lambda I\) and \(B \equiv T = J + \mu S^T\), and for this particular matrix \(A\) and its particular perturbation \(B\) it gives an affirmative answer. In general, however, the answer is complicated, which is documented by a nonsymmetric perturbation of a symmetric tridiagonal Toeplitz matrix. To which
extent our results can be applied to GMRES convergence analysis of more general
problems, e.g., when there exists a well conditioned transformation of the system ma-
trix into a block diagonal form with tridiagonal blocks, remains the subject of further
work.

Acknowledgments. We thank Michael Eiermann and Oliver Ernst for sharing their
unpublished notes [2] and for very stimulating discussions and advice about the sub-
ject matter of this paper. We also thank the anonymous referee for several suggestions
that helped to improve the presentation of the paper. All numerical experiments in
this paper were performed using MATLAB [13].
