# Efficient Deflation for Communication-Avoiding Krylov Subspace Methods 

## Erin Carson

Nicholas Knight, James Demmel
Univ. of California, Berkeley
Monday, June 24, NASCA 2013, Calais, France

## Overview

We derive the Deflated Communication-Avoiding Conjugate Gradient algorithm (Deflated CA-CG), demonstrating that deflation can be implemented while maintaining asymptotic savings in data movement.

1. Background

- What is communication and why should it be avoided?
- Communication-avoiding ( $s$-step) conjugate gradient (CA-CG)
- Deflated Conjugate Gradient method

2. Derivation of Deflated CA-CG
3. Asymptotic communication and computation costs
4. Evaluating tradeoffs in practice

- Performance model and convergence results for model problem

5. Extensions and future work

## What is Communication?

- Algorithms have two costs: communication and computation
- Communication: moving data between levels of memory hierarchy (sequential), between processors (parallel)

- On modern computers, communication is expensive, computation is cheap
- Flop time << 1/bandwidth << latency
- Communication a barrier to scalability (runtime and energy)
- We must redesign algorithms to avoid communication

## How do Krylov Subspace Methods Work?

- A Krylov subspace is defined as

$$
\mathcal{K}_{m}\left(A, r_{0}\right)=\operatorname{span}\left\{r_{0}, A r_{0}, A^{2} r_{0}, \ldots, A^{m-1} r_{0}\right\}
$$

- A Krylov subspace method (KSM) is a projection process onto the subspace $\mathcal{K}$ orthogonal to $\mathcal{L}$
- The choice of $\mathcal{L}$ distinguishes the various methods
- Examples: Conjugate Gradient (CG), Generalized Minimum Residual Methods (GMRES), Biconjugate Gradient (BICG)

KSMs for solving linear systems: in iteration $m$, refine solution $x_{m}$ to $A x=b$ by imposing the condition

$$
x_{m}=x_{0}+\delta, \delta \in \mathcal{K}_{m} \quad \text { and } \quad r_{0}-A \delta \perp \mathcal{L}_{m}
$$

where $r_{0}=b-A x_{0}$

## Communication Limits KSM Performance

In each iteration, the projection process proceeds by:

1. Adding a dimension to the Krylov subspace $\mathcal{K}_{m}$

- Requires sparse matrix-vector multiplication (SpMV)
- Parallel: communicate vector entries with neighbors
- Sequential: read $A$ (and $N$-vectors) from slow memory

2. Orthogonalizing with respect to $\mathcal{L}_{m}$

- Requires inner products
- Parallel: global reductions
- Sequential: multiple reads/writes to slow memory

Dependencies between communication-bound kernels in each iteration limit performance!

## Classical Conjugate Gradient (CG)

Given: initial approximation $x_{0}$ for solving $A x=b$
Let $p_{0}=r_{0}=b-A x_{0}$
for $m=0,1, \ldots$, until convergence do

$$
\begin{aligned}
& \alpha_{m}=\frac{r_{m}^{T} r_{m}}{p_{m}^{T} A p_{m}} \\
& x_{m+1}=x_{m}+\alpha_{m} p_{m} \\
& r_{m+1}=r_{m}-\alpha_{m} A p_{m} \\
& \beta_{m+1}=\frac{r_{m+1}^{T} r_{m+1}}{r_{m}^{T} r_{m}}
\end{aligned}
$$

SpMVs and inner products require communication in each iteration!

$$
p_{m+1}=r_{m+1}+\beta_{m+1} p_{m}
$$

end for

## CA-CG Derivation Overview

In iteration $m+s$ we have the relation

$$
\begin{aligned}
& p_{m+s}, r_{m+s} \in \mathcal{K}_{s+1}\left(A, p_{m}\right)+\mathcal{K}_{s}\left(A, r_{m}\right) \\
& x_{m+s}-x_{m} \in \mathcal{K}_{s}\left(A, p_{m}\right)+\mathcal{K}_{s-1}\left(A, r_{m}\right)
\end{aligned}
$$

Let $V$ be a basis for $\mathcal{K}_{s+1}\left(A, p_{m}\right)+\mathcal{K}_{s}\left(A, r_{m}\right)$, and let Gram matrix $\mathrm{G}=V^{T} V$. For $1 \leq j \leq s$,

$$
p_{m+j}=V p_{j}^{\prime} \quad r_{m+j}=V r_{j}^{\prime} \quad x_{m+j}-x_{m}=V x_{j}^{\prime}
$$

where $p_{j}^{\prime}, r_{j}^{\prime}$, and $x_{j}^{\prime}$ are coordinates for $p_{m+j}, r_{m+j}$, and $x_{m+j}-x_{m}$ in basis $V$.
The product $A p_{m+j-1}$ can be written:

$$
A p_{m+j-1}=A V p_{j-1}^{\prime}=V T p_{j-1}^{\prime}
$$

and inner products can be written:

$$
r_{m+j}^{T} r_{m+j}=r_{j}^{\prime T} G r_{j}^{\prime} \quad \quad p_{m+j-1}^{T} A p_{m+j-1}=p_{j-1}^{\prime T} G T p_{j-1}^{\prime}
$$

## Communication-Avoiding CG

- This formulation allows an $O(s)$ reduction in communication
- Main idea: Split iteration loop into outer loop ( $k$ ) and inner loop ( $j$ )

Outer iteration: 1 communication step

- Compute $V_{k}$ : read $A$ /communicate vectors only once (for well-partitioned A) using matrix powers kernel (see, e.g., Hoemmen et al., 2007)
- Compute Gram matrix $G_{k}=V_{k}^{T} V_{k}$ : one global reduction

Inner iterations: $s$ computation steps

- Perform iterations $s k+j$, for $0 \leq j<s$, with no communication
- Update $(2 s+1)$-vectors of coordinates of $p_{s k+j}, r_{s k+j}, x_{s k+j}-x_{s k}$ in $V_{k}$, replacing SpMVs and inner products
- Quantities either local (parallel) or fit in fast memory (sequential)

Many CA-KSMs (or $s$-step KSMs) derived in the literature:
(Van Rosendale, 1983), (Walker, 1988), (Leland, 1989), (Chronopoulos and Gear, 1989), (Chronopoulos and Kim, 1990, 1992), (Chronopoulos, 1991), (Kim and Chronopoulos, 1991), (Joubert and Carey, 1992), (Bai, Hu, Reichel, 1991), (Erhel, 1995), (De Sturler, 1991), (De Sturler and Van der Vorst, 1995), (Toledo, 1995), (Chronopoulos and Kinkaid, 2001), (Hoemmen, 2010).

## CA-Conjugate Gradient (CA-CG)

Given: initial approximation $x_{0}$ for solving $A x=b$
Let $p_{0}=r_{0}=b-A x_{0}$
for $k=0,1, \ldots$, until convergence do

## via CA Matrix <br> Powers Kernel

 Calculate $P_{k}, R_{k}$, bases for $\mathcal{K}_{s+1}\left(A, p_{s k}\right), \mathcal{K}_{s}\left(A, r_{s k}\right)$, resp. Let $V_{k}=\left[P_{k}, R_{k}\right]$ and compute $G_{k}=V_{k}^{T} V_{k}$ Let $x_{0}^{\prime}=0_{2 s+1}, r_{0}^{\prime}=\left[0_{s+1}^{T}, 1,0_{s-1}^{T}\right]^{T}, p_{0}^{\prime}=\left[1,0_{2 s}^{T}\right]^{T}$ for $j=0, \ldots, s-1$ doGlobal reduction to compute G

$$
\begin{aligned}
& \alpha_{s k+j}=\frac{r_{j}^{\prime T} G_{k} r_{j}^{\prime}}{p_{j}^{\prime T} G_{k} T_{k} p_{j}^{\prime}} \\
& x_{j+1}^{\prime}=x_{j}^{\prime}+\alpha_{s k+j} p_{j}^{\prime} \\
& r_{j+1}^{\prime}=r_{j}^{\prime}-\alpha_{s k+j} T_{k} p_{j}^{\prime} \\
& \beta_{s k+j+1}=\frac{r_{j+1}^{\prime \prime} G_{k} r_{j+1}^{\prime}}{r_{j}^{\prime T} G_{k} r_{j}^{\prime}} \\
& p_{j+1}^{\prime}=r_{j+1}^{\prime}+\beta_{s k+j+1} p_{j}^{\prime}
\end{aligned}
$$

## Local computations

 within inner loop require no communication!end for
Compute $x_{s k+s}=V_{k} x_{s}^{\prime}+x_{s k}, r_{s k+s}=V_{k} r_{s}^{\prime}, p_{s k+s}=V_{k} p_{s}^{\prime}$
end for

## Deflated CG (Saad et al., 2000)

- Deflation: removing eigenvalues that are hard to converge to in order to increase convergence rate
- Convergence of CG governed by $\kappa(A)=\lambda_{N} / \lambda_{1}$
- Where $\lambda_{1} \leq \lambda_{2} \leq \cdots \leq \lambda_{N}$ are eigenvalues of $A$
- Let $W$ be an $N \times c$ matrix to be used in deflation
- Deflated CG is equivalent to CG with system $H^{T} A H \tilde{x}=H^{T} b$ where $H=I-W\left(W^{T} A W\right)^{-1}(A W)^{T}$ is the matrix of the $A$-orthogonal projection onto $W^{\perp_{A}}$
- When columns of $W$ are approximate eigenvectors of $A$ associated with $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{c}, \kappa\left(H^{T} A H\right) \approx \lambda_{N} / \lambda_{c+1}$
- Deflated CG should increase rate of convergence

Can deflation techniques be applied to CA-CG while maintaining asymptotic reduction in communication cost?

## Deflated CG Algorithm (Saad et al., 2000)

Define $W$ to be a length $N \times c$ basis. Compute $W^{T} A W$.
Compute $x_{0}=W\left(W^{T} A W\right)^{-1} W^{T} b$
$r_{0}=b-A x_{0}, \mu_{0}=\left(W^{T} A W\right)^{-1} W^{T} A r_{0}, p_{0}=r_{0}-W \mu_{0}$
for $m=0,1, \ldots$, until convergence do

$$
\alpha_{m}=r_{m}^{T} r_{m} / p_{m}^{T} A p_{m} \quad \text { SpMVs and dot products }
$$

$$
x_{m+1}=x_{m}+\alpha_{m} p_{m}
$$

$$
r_{m+1}=r_{m}-\alpha_{m} A p_{m}
$$

$$
\beta_{m+1}=r_{m+1}^{T} r_{m+1} / r_{m}^{T} r_{m}
$$

$$
\text { Solve } W^{T} A W \mu_{m+1}=W^{T} A r_{m+1} \text { for } \mu_{m+1}
$$

$$
p_{m+1}=\beta_{m+1} p_{m}+r_{m+1}-W \mu_{m+1}
$$

end for

New term due to deflation; requires SpMV and global reduction

## Avoiding Communication in Deflation Process

In Deflated CG, we have

$$
\begin{array}{r}
p_{s k+j}, r_{s k+j} \in \mathcal{K}_{s+1}\left(A, p_{s k}\right)+\mathcal{K}_{s}\left(A, r_{s k}\right)+\mathcal{K}_{s-1}(A, W) \\
x_{s k+j}-x_{s k} \in \mathcal{K}_{s}\left(A, p_{s k}\right)+\mathcal{K}_{s-1}\left(A, r_{s k}\right)+\mathcal{K}_{s-2}(A, W)
\end{array}
$$

To compute $\mu_{s k+j+1}$, we also need

$$
A r_{s k+j+1} \in \mathcal{K}_{s+2}\left(A, p_{s k}\right)+\mathcal{K}_{s+1}\left(A, r_{s k}\right)+\mathcal{K}_{s}(A, W)
$$

Let $V_{k}$ be an $N \times(2 s+3+c s)$ matrix whose columns span this space, i.e.,

$$
V_{k} \in \mathcal{K}_{s+2}\left(A, p_{s k}\right)+\mathcal{K}_{s+1}\left(A, r_{s k}\right)+\mathcal{K}_{s}(A, W)
$$

If we compute $G_{k}=V_{k}^{T} V_{k}$, and extract $Z_{k}=W^{T} V_{k}$ from $G_{k}$, then

$$
W^{T} A r_{s k+j+1}=Z_{k} T_{k} r_{k, j+1}^{\prime}
$$

As in CA-CG, we compute inner products and mult. by $A$ in the inner loop by updating length- $2 s+3+c s)$ coordinate vectors in basis $V_{k}$.

## Deflated CA-CG

Define $W$ to be a length $N \times c$ basis. Compute $W^{T} A W$.
$x_{0}=W\left(W^{T} A W\right)^{-1} W^{T} b, r_{0}=b-A x_{0}, \mu_{0}=\left(W^{T} A W\right)^{-1} W^{T} A r_{0}, p_{0}=r_{0}-W \mu_{0}$

Compute $\mathcal{W}$, a basis for $\mathcal{K}_{S}(A, W)$
for $k=0,1, \ldots$, until convergence do
Compute $P_{k}, R_{k}$, bases for $\mathcal{K}_{s+2}\left(A, p_{s k}\right), \mathcal{K}_{s+1}\left(A, r_{s k}\right)$, resp.
Construct $T_{k}$ such that $A\left[\underline{P}_{k}, \underline{R}_{k}, \underline{\mathcal{W}}\right]=\left[P_{k}, R_{k}, \mathcal{W}\right] T_{k}$

$$
\text { Let } V_{k}=\left[P_{k}, R_{k}, \mathcal{W}\right], \text { compute } G_{k}=V_{k}^{T} V_{k}, Z_{k}=W^{T} V_{k}
$$

$$
\begin{aligned}
& \alpha_{s k+j}=r_{j}^{\prime T} G_{k} r_{j}^{\prime} / p_{j}^{\prime T} G_{k} T_{k} p_{j}^{\prime} \\
& x_{j+1}^{\prime}=x_{j}^{\prime}+\alpha_{s k+j} p_{j}^{\prime} \\
& r_{j+1}^{\prime}=r_{j}^{\prime}-\alpha_{s k+j} T_{k} p_{j}^{\prime} \\
& \beta_{s k+j+1}=r_{j+1}^{\prime T} G_{k} r_{j+1}^{\prime} / r_{j}^{\prime T} G_{k} r_{j}^{\prime}
\end{aligned}
$$

One-time (offline) call to CA matrix powers kernel with $c$ vectors

Additional bandwidth

$$
p_{0}^{\prime}=\left[1,0_{2 s+2+c s}^{T}\right]^{T}, r_{0}^{\prime}=\left[0_{s+2}^{T}, 1,0_{s+c s}^{T}\right]^{T}, x_{0}^{\prime}=0_{2 s+3+c s}
$$ cost once per $s$

$$
\text { for } j=0 \text { to } s-1 \text { do }
$$ iterations

## Local operations, requires no communication

$$
\text { Solve } W^{T} A W \mu_{s k+j+1}=Z_{k} T_{k} r_{j}^{\prime} \text { for } \mu_{s k+j+1}
$$

$$
p_{j+1}^{\prime}=\beta_{s k+j+1} p_{j}^{\prime}+r_{j+1}^{\prime}-\left[0_{2 s+3}^{T}, \mu_{s k+j+1}^{T}, 0_{c(s-1)}^{T}\right]^{T}
$$

end for

$$
x_{s k+s}=V_{k} x_{s}^{\prime}+x_{s k}, r_{s k+s}=V_{k} r_{s}^{\prime}, p_{s k+s}=V_{k} p_{s}^{\prime}
$$

## Computation and Communication Complexity

Model Problem (2D Laplacian), $s$ iterations of parallel algorithm

|  | Flops | Words moved | Messages |
| :---: | :---: | :---: | :---: |
| CG | $O\left(\frac{s N}{p}\right)+O(s)$ | $O(s \sqrt{N / p})+O(s)$ | $O\left(s \log _{2} p\right)+O(s)$ |
| CA-CG | $O\left(\frac{s^{2} N}{p}\right)+O\left(s^{3}\right)$ | $O(s \sqrt{N / p})+O\left(s^{2}\right)$ | $O\left(\log _{2} p\right)$ |
| Deflated <br> CG | $O\left(\frac{c s N}{p}\right)+O\left(c^{2} s\right)$ | $O(s \sqrt{N / p})+O(c s)$ | $O\left(s \log _{2} p\right)+O(s)$ |
| Deflated <br> CA-CG | $O\left(\frac{c s^{2} N}{p}\right)+O\left(c^{2} s^{3}\right)$ | $O(s \sqrt{N / p})+O\left(c s^{2}\right)$ | $O\left(\log _{2} p\right)$ |

Note: offline costs of computing and factoring $W^{T} A W$ omitted for Deflated CG and Deflated CA-CG (as well as computing $\mathcal{K}_{s}(A, W)$ for Deflated CA-CG)

## Is This Efficient in Practice?

- In practice, evaluating tradeoffs between $s$ and $c$ is nontrivial
- Larger $s$ means faster speed per iteration, but can potentially decrease convergence rate in finite precision
- Larger $c$ gives better theoretical convergence rate, but can potentially decrease speed per iteration
- Performance modeling for a specific problem, method, and machine must take both

1. How time per iteration changes with $s$ and $c$
2. How the number of iterations required for convergence changes with $s$ and $c$, and
into account.

- We will demonstrate the tradeoffs involved for our model problem (2D Laplacian) on two large distributed memory machine models

## CA Speedup per Iteration

Plot of modeled speedup per iteration relative to CG for 2 machines, for 2D Laplacian with $N=262,144, p=512$ where

Time $=\gamma($ arithmetic operations $)+\beta($ words moved $)+\alpha$ (messages sent)

Peta

Grid

Peta: $\gamma=2 \cdot 10^{-11}$ (s/flop), $\alpha=10^{-5}(\mathrm{~s}), \quad \beta=2 \cdot 10^{-9}$ (s/word)
Grid: $\gamma=10^{-12}$ (s/flop), $\quad \alpha=10^{-1}(\mathrm{~s}), \quad \beta=25 \cdot 10^{-9}$ (s/word)

## Convergence for Model Problem

## Monomial Basis,

$s=10$

$$
\begin{aligned}
\rho_{0}(A) & =1 \\
\rho_{j}(A) & =A \cdot \rho_{j-1}(A)
\end{aligned}
$$

Matrix: 2D Laplacian(512), $N=262,144$. Right hand side set such that true solution has entries $x_{i}=1 / \sqrt{n}$. Deflated CG algorithm (DCG) from (Saad et al., 2000).

## Total Speedup, Monomial Basis

## Total speedup $=($ speedup per iteration $) \times($ number of iterations(Monomial) $)$

c (\# deflation vectors)

Grid

- Since CA-CG method suffers delayed convergence with monomial basis, higher $s$ doesn't always give better performance (convergence fails for $s>10$ ).
- On Peta, since relative latency is not as bad as on Grid, speedups decrease for large $c$ values.

## Convergence for Model Problem

A better choice of basis leads to stability for higher $s$ values:

Newton Basis,

$$
s=20
$$

$$
\begin{aligned}
& \rho_{0}(A)=1 \\
& \rho_{j}(A)=\left(A-\theta_{j} I\right) \rho_{j-1}(A)
\end{aligned}
$$

where $\theta_{j}$ are Leja-ordered points on $\mathcal{F}(A)$
*For details on better bases for Krylov subspaces, see, e.g., Phillipe and Reichel, 2012.

Matrix: 2D Laplacian(512), $\mathrm{N}=262,144$. Right hand side set such that true solution has entries $x_{i}=1 / \sqrt{n}$. Deflated CG algorithm (DCG) from (Saad, et al., 2000).

## Total Speedup

## Total speedup $=($ speedup per iteration $) \times($ number of iterations(Newton))

Grid

- Peta: Speedup decreases with increasing $c$; CA deflation doesn't lead to significant overall performance improvements over CA-CG
- Grid: since $\mathrm{O}(s)$ speedup from CA techniques remains constant for increasing $c, \mathrm{CA}$ deflation increases overall speedup for all $s$ values!

## Conclusions and Future Work

- Summary
- Proof-of-concept that deflation techniques can be implemented in CA-CG in a way that still avoids communication
- Asymptotic bounds confirm that Deflated CA-CG maintains the $O(s)$ reduction in latency over CG and Deflated CG
- Performance modeling demonstrates nontrivial tradeoffs between speed per iteration and convergence rate for different methods
- Future Work
- Extending other deflation techniques to CA methods
- Solving (slowly-changing) series of linear systems (recycling Krylov subspaces)
- Reorthogonalization to fix instability in Deflated CA-CG ( $r \perp W$ fails in finite precision, set $\left.r=\left(I-W\left(W^{T} W\right)^{-1} W^{T}\right) r\right)$ (Saad et al., 2000)
- Equivalent 'augmented' formulations (Gaul et al., 2013)
- Claim: CA deflation can be applied to other deflated Krylov methods
- GMRES, MINRES, BICG(STAB), QMR, Arnoldi, Lanczos, etc., see, e.g., (Gutknecht, 2012)

## CA-CG Derivation Overview

In iteration $s k+j$, for $s>0,0 \leq j \leq s$, we exploit the relation

$$
\begin{aligned}
& p_{s k+j}, r_{s k+j} \in \mathcal{K}_{s+1}\left(A, p_{s k}\right)+\mathcal{K}_{s}\left(A, r_{s k}\right) \\
& x_{s k+j}-x_{s k} \in \mathcal{K}_{s}\left(A, p_{s k}\right)+\mathcal{K}_{s-1}\left(A, r_{s k}\right)
\end{aligned}
$$

Let $V_{k}$ be a matrix whose columns span $\mathcal{K}_{s+1}\left(A, p_{s k}\right)+\mathcal{K}_{s}\left(A, r_{s k}\right)$.

Then for iterations $s k+1$ through $s k+s$, we can implicitly update the length n vectors $p_{s k+j}, r_{s k+j}$, and $x_{s k+j}-x_{s k}$ by updating their coordinates (length $2 s+1$ vectors) in basis $V_{k}$.

$$
p_{s k+j}=V_{k} p_{k, j}^{\prime} \quad r_{s k+j}=V_{k} r_{k, j}^{\prime} \quad x_{s k+j}-x_{s k}=V_{k} x_{k, j}^{\prime}
$$

## CA-CG Derivation Overview

In iteration $s k+j$, for $s>0,0 \leq j \leq s$, we exploit the relation

$$
\begin{aligned}
& p_{s k+j}, r_{s k+j} \in \mathcal{K}_{s+1}\left(A, p_{s k}\right)+\mathcal{K}_{s}\left(A, r_{s k}\right) \\
& x_{s k+j}-x_{s k} \in \mathcal{K}_{s}\left(A, p_{s k}\right)+\mathcal{K}_{s-1}\left(A, r_{s k}\right)
\end{aligned}
$$

If we compute basis $V_{k}$ for $\mathcal{K}_{s+1}\left(A, p_{s k}\right)+\mathcal{K}_{s}\left(A, r_{s k}\right)$ and compute Gram matrix $G_{k}=V_{k}^{T} V_{k}$, then for iterations $0 \leq j<s$ we can implicitly update the length n vectors $p_{s k+j}, r_{s k+j}$, and $x_{s k+j}-x_{s k}$ by updating their coordinates (length $2 s+1$ vectors) in basis $V_{k}$.

$$
p_{s k+j}=V_{k} p_{k, j}^{\prime} \quad r_{s k+j}=V_{k} r_{k, j}^{\prime} \quad x_{s k+j}-x_{s k}=V_{k} x_{k, j}^{\prime}
$$

The product $A p_{s k+j}$ can be represented implicitly in basis $V_{k}$ by $B_{k} p_{k, j}^{\prime}$, since

$$
A p_{s k+j}=A V_{k} p_{k, j}^{\prime}=V_{k} B_{k} p_{k, j}^{\prime}
$$

and we can write dot products as

$$
r_{s k+j}^{T} r_{s k+j}=r_{k, j}^{\prime T} G_{k} r_{k, j}^{\prime} \quad p_{s k+j}^{T} A p_{s k+j}=p_{k, j}^{\prime T} G_{k} B_{k} p_{k, j}^{\prime}
$$

## CA-CG Derivation Overview

The product $A p_{s k+j}$ can be represented implicitly in basis $V_{k}$ by $B_{k} p_{k, j}^{\prime}$, since

$$
A p_{s k+j}=A V_{k} p_{k, j}^{\prime}=V_{k} B_{k} p_{k, j}^{\prime}
$$

If we compute $G_{k}=V_{k}^{T} V_{k}$, we can write dot products as

$$
r_{s k+j}^{T} r_{s k+j}=r_{k, j}^{\prime T} G_{k} r_{k, j}^{\prime} \quad p_{s k, f j}^{T} A p_{s k+j}=p_{k, j}^{\prime T} G_{k} B_{k} p_{k, j}^{\prime}
$$

$B_{k}$ and $G_{k}$ are small $O(s) \times O(s)$ matrices that fits in fast/local memory; Multiplication by $B_{k}$ and $G_{k}$ require no communication!

## Convergence in Finite Precision

- CA-KSMs are mathematically equivalent to classical KSMs
- But have different behavior in finite precision!
- Roundoff error causes delay of convergence
- Bounds on magnitude of roundoff error increase with $s$
- In solving practical problems, roundoff error can limit performance
- If \# iterations increases more than time per iteration decreases due to CA techniques, no speedup expected!
- To perform a practical performance comparison amongst CG, Deflated CG, CA-CG and Deflated CA-CG, we must combine speedup per iteration with the total number of iterations for each method

## Detailed Complexity Analysis: CG

$F l o p s_{C G}=2 s-\frac{2 s}{p}+\frac{19 n s}{p}$
$W o r d s_{C G}=2 s-\frac{2 s}{p}+4 s \sqrt{n / p}$

## Better Polynomial Bases

In general, columns $v_{i+1}$ of $V$ computed by the 3 -term recurrence

$$
v_{i+1}=\left(\left(A-\hat{\alpha}_{i} I\right) v_{i}-\hat{\beta}_{i} v_{i-1}\right) / \hat{\gamma}_{i}
$$

Scaled Monomial: For scalars $\left\{\sigma_{i}\right\}_{i=1}^{S}$,

$$
\hat{\alpha}_{i}=0, \hat{\beta}_{i}=0, \hat{\gamma}_{i}=\sigma_{i}
$$

Newton: For Leja-ordered Ritz values $\left\{\theta_{i}\right\}_{i=1}^{S}$ and scalars $\left\{\sigma_{i}\right\}_{i=1}^{S}$

$$
\hat{\alpha}_{i}=\theta_{i}, \hat{\beta}_{i}=0, \hat{\gamma}_{i}=\sigma_{i}
$$

Chebyshev: Given bounding ellipse for spectrum with foci at $d \pm c$, the scaled and shifted polynomials are

$$
\begin{array}{rlrl}
\tilde{\tau}_{i}(z) & =\tau_{i}((d-z) / c) / \sigma_{i}, \\
\hat{\alpha}_{i}=d, & \hat{\beta}_{i} & =-\frac{c \sigma_{i}}{2 \sigma_{i+1}}, \quad \hat{\gamma}_{i}=-\frac{c \sigma_{i+1}}{2 \sigma_{i}}
\end{array}
$$

## Leja Ordering

Let $\mathbb{S}$ be a compact set in $\mathbb{C}$. (Note that here $\mathbb{S}$ is set of approx. Ritz values). Then a Leja ordering can be computed by

$$
\begin{gathered}
\theta_{1}=\operatorname{argmax}_{z \in \mathbb{S}}|z| \\
\theta_{i+1}=\operatorname{argmax}_{z \in \mathbb{S}} \prod_{k=0}^{i}\left|z-z_{k}\right|
\end{gathered}
$$

Leja (1957)

Many references for using different polynomials for Krylov subspace calculation:
See, e.g., Philippe and Reichel (2012), Bai et al. (1994), Joubert and Carey (1992), de Sturler and van der Vorst (1994, 1995), Erhel (1995).

## Residual Replacement Strategy

- Van der Vorst and Ye (1999) : Residual replacement used in combination with group-update to improve the maximum attainable accuracy
- Given computable upper bound for deviation of residuals, replacement steps chosen to satisfy two constraints:

1. Deviation must not grow so large that attainable accuracy is limited
2. Replacement must not perturb Lanczos recurrence relation for computed residuals such that convergence deteriorates

- When the computed residual converges to level $O(\varepsilon)\|A\|\|x\|$ strategy reduces true residual, to level $O(\varepsilon)\|A\|\|x\|$
- We devise an analogous strategy for CA-CG and CA-BICG
- Our strategy does not asymptotically increase communication or computation!
$s=4$

$s=12$

$s=8$

- Matrix: consph (FEM), SPD, $N=$ $8.3 E 4, N Z=6 E 6, \kappa(A) \approx 9.7 E 3$.
- In all tests \#replacements $\leq 5$.
- Orders of magnitude improvement in accuracy for little additional cost!
- But doesn't fix slow convergence due to ill-conditioned basis.

## Total Speedup, Monomial Basis

Total speedup $=($ speedup per iteration $) \times($ number of iterations(Monomial) $)$

Peta

Grid

Since the CA-CG method without deflation suffers delayed convergence, deflation results in performance improvements on both machines (note that delayed convergence also means that higher s doesn't always give better performance for monomial). On Peta, since relative latency is not as bad as on Grid, speedups start to decrease for large c values.

## Overlapping Communication and Computation

Plot of modeled speedup per iteration relative to CG for 2 machines, for 2D Laplacian with $n=262,144, p=512$ where

Time $=\max (\gamma($ arithmetic operations $), \beta($ words moved $)+\alpha($ messages sent $))$

## Total Speedup with Overlap (Newton)

## Total speedup $=($ speedup per iteration $) \times($ number of iterations(Newton))

Grid

Peta: Overlapping communication and computation decreases cost of increasing c, so deflation results in performance improvement
Grid: Overlapping communication and computation doesn't change anything, since extremely communication bound

## Total Speedup with Overlap (Monomial)

Total speedup $=($ speedup per iteration $) \times($ number of iterations(Monomial) $)$

Grid

Peta: Overlapping communication and computation decreases cost of increasing $c$; deflation results in speedup (but since convergence decreases $s$, best speedup at $s=8$. Grid: Overlapping communication and computation doesn't change anything, since extremely communication bound

## The Matrix Powers Kernel

- Compute dependencies up front for computing $A v, A^{2} v, \ldots, A^{s} v$
- $s$ steps of the transitive closure of $A$
- Only need to read $A$ once assuming $A$ is well-partitioned

Figures: [MHDY09]
