# Exploiting Low-Rank Structure in Computing Matrix Powers with Applications to Preconditioning 

Erin C. Carson<br>Nicholas Knight, James Demmel, Ming Gu U.C. Berkeley

## Motivation: The Cost of an Algorithm

- Algorithms have 2 costs: Arithmetic (flops) and movement of data (communication)
- Assume simple model with 3 parameters:
- $\alpha$-Latency, $\beta$ - Reciprocal Bandwidth, $\gamma$ - Flop Rate
- Time to move n words of data is $\alpha+\mathrm{n} \beta$

Sequential

- Problem: Communication is the bottleneck on modern architectures
$-\alpha$ and $\beta$ improving at much slower rate than $\gamma$
- Solution: Reorganize algorithms to avoid communication

Parallel

## Motivation: Krylov Subspace Methods

- Krylov Subspace Methods (KSMs) are iterative methods commonly used in solving large, sparse linear systems of equations
- Krylov Subspace of dimension $k$ with matrix $A$ and vector $v$ :

$$
\mathcal{K}_{k}(A, v)=\operatorname{span}\left\{v, A v, A^{2} v, \ldots, A^{k-1} v\right\}
$$

- Work by iteratively adding a dimension to the expanding Krylov Subspace (SpMV) and then choosing the "best" solution from that subspace (vector operations)
- Problem: Krylov Subspace Methods are communication-bound
- SpMV and global vector operations in every iteration

## Avoiding Communication in Krylov Subspace Methods

- We need to break the dependency between communication bound kernels and KSM iterations
- Idea: Expand the subspace $s$ dimensions ( $s$ SpMVs with $A$ ), then do $s$ steps of refinement
- To do this we need two new Communication-Avoiding kernels
- "Matrix Powers Kernel" replaces SpMV

- "Tall Skinny QR" (TSQR) replaces orthogonalization operations

## The Matrix Powers Kernel

- Given $A, v, s$, and degree $j$ polynomials $\rho_{j}, j=0: s$ defined by a 3-term recurrence, the matrix powers kernel computes

$$
\left\{\rho_{0}(A) v, \rho_{1}(A) v, \rho_{2}(A) v, \ldots, \rho_{s}(A) v\right\}
$$

- The matrix powers kernel computes these basis vectors only reading/communicating $A o(1)$ times!
- Parallel case: Reduces latency by a factor of $s$ at the cost of redundant computations

Parallel Matrix Powers algorithm for tridiagonal matrix example. 4 processors, $n=40, s=3$

## Matrix Powers Kernel Limitations

- Asymptotic reduction in communication requires that $A$ is wellpartitioned
- "Well-partitioned"- number of redundant entries required by each partition is small - the graph of our matrix has a good cover
- With this matrix powers algorithm, we can't handle matrices with dense components
- Matrices with dense low-rank components appear in many linear systems (e.g., circuit simulations, power law graphs), as well as preconditioners (e.g., Hierarchical Semiseparable (HSS) matrices)
- Can we exploit low-rank structure to avoid communication in the matrix powers algorithm?

## Blocking Covers Approach to Increasing Temporal Locality

- Relevant work:
- Leiserson, C.E. and Rao, S. and Toledo, S. Efficient out-of-core algorithms for linear relaxation using blocking covers. Journal of Computer and System Sciences, 1997.
- Blocking Covers Idea:
- According to Hong and Kung's Red-Blue Pebble game, we can't avoid data movement if we can't find a good graph cover
- What if we could find a good cover by removing a subset of vertices from the graph? (i.e., connections are locally dense but globally sparse)
- Relax the assumption that the DAG must be executed in order
- Artificially restrict information from passing through removed vertices ("blockers") by treating their state variables symbolically, maintain dependencies among symbolic variables as matrix

## Blocking Covers Matrix Powers Algorithm

- Split $A$ into sparse and low-rank dense parts, $A=D+U V^{T}$
- In our matrix powers algorithm, the application of $V^{T}$ requires communication, so we want to limit the number these operations
- Then we want to compute (assume monomial basis for simplicity)

$$
\left\{v, A v, \ldots, A^{s} v\right\}=\left\{v,\left(D+U V^{T}\right) v, \ldots,\left(D+U V^{T}\right)^{s} v\right\}
$$

- We can write the $j t h$ basis vector as

$$
c_{j}=\left(D+U V^{T}\right)^{j} v=D c_{j-1}+U V^{T} c_{j-1}=D^{j} v+\sum_{k=1}^{j} D^{k-1} U V^{T} c_{j-k}
$$

- Where the $V^{T} c_{j-k}$ quantities will be the values of the "blockers" at each step.
- We can premultiply the previous equation by $V^{T}$ to write a recurrence:

$$
V^{T} c_{j}=V^{T} D^{j} v+\sum_{k=1}^{j}\left(V^{T} D^{k-1} U\right)\left(V^{T} c_{j-k}\right)
$$

## Blocking Covers Matrix Powers Algorithm

Phase 0: Compute $\left\{U, D U, D^{2} U, \ldots, D^{s-2} U\right\}$ using the matrix powers kernel. Premultiply by $V^{T}$.

Phase 1: Compute $\left\{v, D v, D^{2} v, \ldots, D^{s-1} v\right\}$ using the matrix powers kernel. Premultiply by $V^{T}$.

Phase 2: Using the computed quantities, each processor backsolves for $V^{T} c_{j}$ for $j=1: s-1$

Phase 3: Compute the $c_{j}$ vectors, interleaving the matrix powers kernel with local $U V^{T} c_{j-1}$ multiplications

$$
\begin{aligned}
V^{T} c_{j} & =V^{T} D^{j} v+\sum_{k=1}^{j}\left(V^{T} D^{k-1} U\right)\left(V^{T} c_{j-k}\right) \\
c_{j} & =D c_{j-1}+U V^{T} c_{j-1}
\end{aligned}
$$

## Asymptotic Costs

| Phase | Flops | Words Moved | Messages |
| :---: | :---: | :---: | :---: |
| 0 | $A k x(D, U, s-2)+O\left(\frac{\mathrm{sr} r^{2} n}{p}\right)$ | $O\left(s r^{2} \log p\right)+$ <br> $r\left(\right.$ ghost zones, $\left.D^{s-2}\right)$ | $O(\log p)$ |
| 1 | $A k x(D, v, s-1)+O\left(\frac{\mathrm{~s} n}{p}\right)$ | $O(s r \log p)+$ <br> $\left(\right.$ ghost zones, $\left.D^{s-1}\right)$ | $O(\log p)$ |
| 2 | $O\left(s^{2} r^{2}\right)$ | 0 | 0 |
| 3 | $A k x(D, v, s)+O\left(\frac{s r n}{p}\right)$ | 0 | 0 |

|  | Flops | Words Moved | Messages |
| :---: | :---: | :---: | :---: |
| Total Online <br> $(\mathrm{CA})$ | $2 \times \operatorname{Akx}(D, v, s)+O\left(\frac{\mathbf{S r n}}{p}\right)$ | $O(\operatorname{sr} \log p)+$ <br> $\left(\right.$ ghost zones,$\left.D^{s-1}\right)$ | $O(\log p)$ |
| Standard Alg. | $\mathrm{s} \times A k x(D, v, 1)+O\left(\frac{\mathrm{Srn}}{p}\right)$ | $O(\operatorname{sr} \log p)+$ <br> $s($ ghost zones, $D)$ | $O(s \log p)$ |

## Extending the Blocking Covers Matrix Powers Algorithm <br> to HSS Matrices

## HSS Structure:

- $l$-level binary tree
- Off-diagonal blocks have rank $r$
- Can write $A$ hierarchically:

$$
\begin{aligned}
& D_{0 ; 1}=A \\
& D_{k ; i}=\left(\begin{array}{c}
D_{k+1 ; 2 i-1} \\
U_{k+1 ; 2 i} B_{k+1 ; 2 i, 2 i-1} V^{T}{ }_{k+1 ; 2 i-1}
\end{array}\right.
\end{aligned}
$$

$$
\begin{gathered}
\left.U_{k+1 ; 2 i-1} B_{k+1 ; 2 i-1,2 i} V^{T}{ }_{k+1 ; 2 i}\right) \\
D_{k+1 ; 2 i}
\end{gathered}
$$

- Can define translations for row and column bases, i.e:

$$
U_{k ; i}=\binom{U_{k+1 ; 2 i-1} R_{k+1 ; 2 i-1}}{U_{k+1 ; 2 i} R_{k+1 ; 2 i}} \quad V_{k ; i}=\binom{V_{k+1 ; 2 i-1} W_{k+1 ; 2 i-1}}{V_{k+1 ; 2 i} W_{k+1 ; 2 i}}
$$

## Exploiting Low-Rank Structure

- Matrix can be written as $D+U S V^{T}$
- S composed of $R, W, B$ 's translation operations ( $S$ is not formed explicitly)

$$
+
$$

$V^{T}$

## Parallel HSS Akx Algorithm

- Data Structures:
- Assume $p=2^{l}$ processors
- Each processor $i$ owns
- $D_{i}$, dense diagonal block, dimension ( $n / p \times n / p$ )
- $V_{i}$, dimension $(r \times n / p)$
- $U_{i}$, dimension $(r \times n / p)$
- $x_{i},(n / p \times 1)$ piece of source vector
- All matrices $R, W, B$,
- These are all small $O\left(2^{l} r^{2}\right)$ sized matrices, assumed they fit on each proc.

## Extending the Algorithm

- Only change needed is in Phase 2 (backsolving for $V^{T} c_{j}$ )
- Before, we computed, for $j=1$ : $s-1$

$$
V^{T} c_{j}=V^{T} D^{j} v+\sum_{k=1}^{j}\left(V^{T} D^{k-1} U\right)\left(V^{T} c_{j-k}\right)
$$

- Now, we can exploit hierarchical semiseparability:
- For $j=1: s-1$, first compute

$$
g_{l}=V^{T} D^{j} v+\sum_{k=1}^{j}\left(V^{T} D^{k-1} U\right)\left(V^{T} c_{j-k+1}\right)
$$

## Extending the Algorithm

- Then each processor locally performs upsweep and downsweep:
for $y=l-1$ : 1

$$
g_{y}=\left[\begin{array}{lllll}
{\left[\begin{array}{llll}
W^{T} & y+1 ; 1 & W^{T}{ }_{y+1 ; 2}
\end{array}\right]} & & \\
& & \ddots & & \\
& & & {\left[W^{T}{ }_{y+1 ; 2\left(2^{y}\right)-1}\right.} & \left.W^{T}{ }_{y+1 ; 2\left(2^{y}\right)}\right]
\end{array}\right] g_{y+1}
$$

$$
f_{0}=(0)
$$

for $y=0: l-1$

$$
f_{y+1}=\left[\begin{array}{lll}
B_{y+1 ; 1,2} & & \\
& \ddots & \\
& & B_{y+1 ; 2^{y+1}, 2^{y+1}-1}
\end{array}\right] g_{y}+\left[\begin{array}{|ccc}
{\left[\begin{array}{l}
y+1 ; 1 \\
R_{y+1 ; 2}
\end{array}\right]} & & \\
& \ddots & \\
& & {\left[\begin{array}{c}
R_{y+1 ; 2^{y+1}-1} \\
R_{y+1 ; 2^{y+1}}
\end{array}\right]}
\end{array}\right] f_{y}
$$

$$
V^{T} c_{j}=f_{l}
$$

- At the end, each processor has locally computed the $V^{T} c_{j}$ recurrence for the $j^{t h}$ iteration (additional $s r^{2} p$ flops in Phase 2)

## HSS Matrix Powers Communication and Computation Cost

- Offline (Phase 0)
- Flops: $\operatorname{Akx}(D, U, s)+O\left(\frac{s r^{2} n}{p}\right)$
- Words Moved: $O\left(r^{2} s \log p\right)$
- Messages: $O(\log p)$
- Online (Phases 1, 2, 3)
- Flops: $2 \times \operatorname{Akx}(D, x, s)+O\left(\frac{s r n}{p}\right)$
- Words Moved: $O(r s \log p)$
- Messages: $O(\log p)$
- Same flops (asymptotically) as $\boldsymbol{s}$ iterations of standard HSS Matrix-Vector Multiply algorithm
- Asymptotically reduces messages by factor of $s$ !

## Future Work

- Auto-tuning: Can we automate the decision of which matrix powers kernel variant to use?
- What should be the criteria for choosing blockers?
- Stability
- How good is the resulting (preconditioned) Krylov basis?
- Performance studies
- How does actual performance of HSS matrix powers compare to $s$ HSS matrix-vector multiplies?
- Extension to other classes of preconditioners
- Can we apply the blocking covers approach to other algorithms with similar computational patterns?
